Sol. The oscillator frequency should be same as proton's cyclotron frequency.

$$B = 2\pi m v/q$$

$$= 6.3 \times 1.67 \times 10^{-27} \times 10^7 / (1.6 \times 10^{-19})$$

Final velocity of protons is

$$v = r \times 2\pi f = 0.6 \text{ m} \times 6.3 \times 10^7 = 3.78 \times 10^7 \text{ m/s.}$$

$$E = \frac{1}{2} mv^2 = 1.67 \times 10^{-27} \times 14.3 \times 10^{14} / (2 \times 1.6 \times 10^{-13}) = 7 \text{ MeV}$$

41. Ans. (3)

Sol. When the current through the element is very small, heating effects can be ignored and the temperature T_1 of the element is the same as room temperature. When the toaster is connected to the supply, its initial current will be slightly higher than its steady value of 2.68 A. But due to heating effect of the current, the temperature will rise. This will cause an increase in resistance and a slight decrease in current. In a few seconds, a steady state will be reached when temperature will rise no further, and both the resistance of the element and the current drawn will achieve steady values. The resistance R_2 at the steady temperature T_2 is

$$R_2 = \frac{230V}{2.68A} = 85.8\Omega$$

Using the relation

$$R_2 = R_1 [1 + \alpha (T_2 - T_1)]$$

with $\alpha = 1.70 \times 10^{-4} \text{ } ^\circ\text{C}^{-1}$, we get

$$T_2 - T_1 = \frac{(85.8 - 75.3)}{(75.3) \times 1.70 \times 10^{-4}} = 820 \text{ } ^\circ\text{C}$$

that is, $T_2 = (820 + 27.0) \text{ } ^\circ\text{C} = 847 \text{ } ^\circ\text{C}$

Thus, the steady temperature of the heating element (when heating effect due to the current equals heat loss to the surroundings) is $847 \text{ } ^\circ\text{C}$.

Sol. While the slider is in the middle of the potentiometer only half of its resistance ($R_0/2$) will be between the points A and B. Hence, the total resistance between A and B, say, R_1 , will be given by the following expression:

$$\frac{1}{R_1} = \frac{1}{R} + \frac{1}{(R_0/2)}$$

$$R_1 = \frac{R_0 R}{R_0 + 2R}$$

The total resistance between A and C will be sum of resistance between
